how to initialize a Repository

→ usually when we open a folder it is just a folder so whenever Git tracking that folder it will became a repository

→ for converting a folder to a repository we should have **.git** file in the folder

→ for that we have to create configuration file with name and email

```
>> git config --global user.name "pavan kumar"
>> git config --global user.email "pavan123@gmail.com"
```

→ This will create a global configuration with name and email

→ Now for initializing a new repository run

```
>> git init
```

→ it will create a .git file in your folder

Important Commands:

1. git status → Tells about which branch currently we are and how many commits have been done

→ So usually git starts with a branch called master
→ and if we want to work with git/github we need to register a branch on first commit
→ That is main branch

Initial Steps

→ create a File Testing.txt

```
>> git add .
>> git commit -m "first commit"
```

→ Now register a New Branch (Because Initial branch was Master we can't work directly in Master)

→ now we have one commit so we are in master branch

2. git branch → returns branch Name Currently where we are working
